

Note: my solutions feel abominably long! I am unsure how to rectify this; the solution I want to write is always about two lines and says "this is rather obvious." For instance, problem 21 $\mathbf{Grp} \rightarrow \mathbf{Cat}$ I could answer by saying "we send groups to their one-element groupoids and group homomorphisms to homomorphisms on the morphisms of those one element-groupoids, which we recognize as the group itself." or for 24: "First, we recognize that a directed graph morphism ought to send sources to sources and targets to targets. Then, we recognize that if you get rid of all the identity and composition information, categories look like directed graphs. Finally, we go the other way and send directed graphs to categories with the same underlying set as the graph, and make sure that we can concatenate paths to not worry about composition. Also notice that functions between directed graphs like we defined in part 1 look pretty much the same as functors."

That doesn't feel sufficient though, and in trying to explain the details, it gets terribly bogged down...

Problem 21. Write out the details of the functors $\mathbf{Poset} \rightarrow \mathbf{CAT}$ and $B : \mathbf{Grp} \rightarrow \mathbf{CAT}$ we have discussed in class.

Solution.

For notational convenience, I will use capital P_i to refer to posets in the category poset, which will each have a corresponding set p_i and relation \leq_{P_i} . Between two posets P_i, P_j there can exist morphisms (order-preserving functions), which I'll denote F_{ij} with more indices as needed.

The functor $A : \mathbf{Poset} \rightarrow \mathbf{CAT}$ operates as follows: A maps P_i to P_i 's corresponding category \bar{P}_i : a category with elements p_i and an arbitrary morphism $*_{ab}$ between each $a \leq_{P_i} b \in p_i$. (Composition in \bar{P}_i is given by $*_{bc} \circ *_{ab} = *_{ac}$, i.e. transitivity of the relation)

Given P_1, P_2 , A maps $\mathbf{Poset}(P_1, P_2) \rightarrow \mathbf{CAT}(\bar{P}_1, \bar{P}_2)$ where an order-preserving function $f : P_1 \rightarrow P_2$ has $a \leq_{P_1} b \implies f(a) \leq_{P_2} f(b)$ is mapped to a functor $F : \bar{P}_1 \rightarrow \bar{P}_2$ mapping a to $f(a)$ and $*_{ab}$ to $*_{f(a)f(b)}$.

We need to first show that F is a functor, then that A is a functor.

The identities of each category \bar{P}_i are the morphisms $*_{aa}$, which exist by definition of poset. These clearly map to identities $*_{f(a)f(a)}$ under F . We also have $F(*_{bc} \circ *_{ab}) = F(*_{ac}) = *_{fafc} = *_{fbfc} \circ *_{fafb} = F(*_{bc}) \circ (*_{ab})$, where there only being at most one morphism between any two elements makes all of these statements sensible. Hence, F is a functor.

Now, we will show that A is a functor. The identities in \mathbf{Poset} are the identity functions. The identities in \mathbf{CAT} are the identity functors that do nothing to a category. It is hopefully quite obvious that $A(1_{P_i}) = 1_{\bar{P}_i}$. Let f, g be order preserving functions. $A(f \circ g)$ must send a to $f(g(a))$ and $*_{ab}$ to $*_{fgafgb}$, the same action as $F \circ G = A(f) \circ A(g)$. Hence, A respects composition and is a functor!

We will perform a similar argument for B , but I will omit some of the painful details. B takes a group G to the one-element groupoid BG with element $*$ and morphisms G with composition given by multiplication within G . B takes a group homomorphism $\phi : G \rightarrow H$ to a functor $F : BG \rightarrow BH$ which takes the single element of BG to the single element of BH and takes the morphisms of BG , which is to say, G , to B via

$B(BG(*, *)) = BH(*, *)$. In other words, F acts on the morphisms of BG by group homomorphism: if $g \in G$, $B(\phi)(g) = \phi(g)$, where $\phi(g)$ is understood as a morphism (group element) in the group BH .

1_G is the identity in **Grp**, a function that takes the group G to itself. $B(1_G)(g) = 1_G(g) = g$, so B takes the identity group homomorphism to the identity functor.

Given two group homomorphisms, $\phi : H \rightarrow K, \psi : G \rightarrow H$, with $B(\phi) = F, B(\psi) = F'$. $B(\phi \circ \psi)$ takes the morphisms of BG to the morphisms of BK . The morphisms are just group elements. Let $g \in G$. Then, $B(\phi \circ \psi)(g) = (\phi \circ \psi)(g) = (F \circ F')(g) = (B(\phi) \circ B(\psi))(g)$. This holds for all g , and we conclude $B(\phi \circ \psi) = F \circ F'$. Hence, B is a functor.

Problem 24. A directed graph $X = (X_v, X_e, s, t)$ consists of a vertex set X_v , an edge set X_e and two functions $s, t : X_e \rightarrow X_v$ the source and target. An edge f from 1 to 2 $\in X_v$ can be thought of an arrow from $s(f)$ to $t(f)$

1. Construct a category of directed graphs **DGraph**
2. Let **Cat** be the category of small categories (objects form a set). Prove that there's a forgetful functor $U : \mathbf{Cat} \rightarrow \mathbf{DGraph}$ sending \mathcal{C} to the directed graph $U\mathcal{C}$ with $U\mathcal{C}_v = ob(\mathcal{C})$ and $U\mathcal{C}_e = \coprod_{a,b \in ob\mathcal{C}} \mathcal{C}(a, b)$.
3. Construct a functor $P : \mathbf{DGraph} \rightarrow \mathbf{Cat}$ where PX has objects X_v and morphisms directed paths

Solution.

1. The objects of **DGraph** are directed graphs, with morphisms $F : D^1 \rightarrow D^2$ a pair of functions $F_V : D_v^1 \rightarrow D_v^2, F_E : D_e^1 \rightarrow D_e^2$ such that $s^2 \circ F_E = F_V \circ s^1$ (the source of the image of any edge is the image of the source of that edge) and $t^2 \circ F_E = F_V \circ t^1$ (the target of the image of any edge is the image of the target of that edge) and composition given by function composition in the vertex part and edge part separately.

We first show that composition is sensible (and associative!). Suppose we have $F : D^1 \rightarrow D^2, G : D^2 \rightarrow D^3, H : D^3 \rightarrow D^4$. Suppose e_1 is an edge with source v_1 and target u_1 . $F_E(e_1) = e_2$ with $s^2(e_2) = F_V(v_1)$ and $t^2(e_2) = F_V(u_1)$. We will give these sources and targets the names v_2 and u_2 . Each edge can only have one source and target, so giving those sources and targets names is not an issue. We do the same for v_i and u_i in general. $G \circ F$ has components $G_E \circ F_E$ and $G_V \circ F_V$. By associativity of function composition, we conclude that if $s^2 \circ F_E = F_V \circ s^1$ and $s^3 \circ G_E = G_V \circ s^2$, then $s^3 \circ G_E \circ F_E = G_V \circ F_V \circ s^1$, then $G \circ F$ obeys our relevant conditions. The same argument gives us associativity of our morphisms $(H \circ G) \circ F = H \circ (G \circ F)$.

The identity morphism 1_D has functions the identity function. Given $F : D^1 \rightarrow D^2$, $F \circ 1_{D^1}$ has its component parts $F_E \circ 1_{D_e^1} = F_E$ and $F_V \circ 1_{D_v^1} = F_V$. Hence, the identity is a right identity. The same argument on the left gives us the necessary statement.

Yay! Category!

2. We take a category and the bones of the functor U as in the question. We need to show how U gives us s and t and show that that construction gives us a directed graph, define what U does to morphisms in **Cat**, and prove that U is a functor by showing it takes identities to identities and respects composition.

Let $a, b \in \text{ob}(\mathcal{C})$ be fixed. Given an edge $e \in \mathcal{C}(a, b)$, we define $s(e) = a$ and $t(e) = b$. This, gives us a directed graph. Now, we take a morphism $F : \mathcal{B} \rightarrow \mathcal{C}$, which is a functor. We will define UF to be the pair F_E, F_V as in part 1. More explicitly, F_E is the morphism part of F and F_V is the object part of F . That is to say, $UF = F$. Notice that $s(Ff) = F(a)$, $F(s(f)) = F(a)$, where we implicitly use the object part of F as F_E . The same argument holds for targets. Hence, UF is indeed a **DGraph** morphism.

The identity morphism in $1_{\mathcal{C}} \in \mathbf{Cat}$ maps to $F_E : \coprod_{a,b \in \text{ob}\mathcal{C}} \mathcal{C}(a, b) \rightarrow \coprod_{a,b \in \text{ob}\mathcal{C}} \mathcal{C}(a, b)$ and $F_V : \text{ob}(\mathcal{C}) \rightarrow \text{ob}(\mathcal{C})$ such that $s \circ F_E = F_V \circ s$ and ditto for targets. Given a, b objects in \mathcal{C} and f a morphism between them, we notice $s(F_E(f)) = s(f) = a$ and $F_V(s(f)) = F_V(f)$, and so $F_V(f) = a$. The same holds for targets. Thus, $U1_{\mathcal{C}} = 1_{U\mathcal{C}}$.

Given two morphisms $\mathcal{A} \xrightarrow{F} \mathcal{B} \xrightarrow{G} \mathcal{C}$ in **Cat**, $U(G \circ F)$ is the pair we denote $(G \circ F)_E, (G \circ F)_V$. $G \circ F$ gives us a perfectly sensible function on objects, and similarly on morphisms, as G and F are functors. In particular, $(G \circ F)(a) = G(F(a))$ and $(G \circ F)(f : a \rightarrow a') = G(F(f)) : GFa \rightarrow GFa'$. $U(G \circ F) = G \circ F = U(G) \circ U(F)$. Hence, U is a functor!

More explicitly, U is a functor that "forgets" all the details of morphism composition and identities in the underlying category, and just preserves the category written as a diagram.

3. Given a directed graph, most of our work is already done. The issue comes from morphism composition and identities. For instance, we may have edges AB and BC in the dgraph, but no edges AA and AC that we would need for the full categorification of the dgraph. So, PX must have the following: $\text{ob}(PX) = X_v$.

$$PX(v, u) = \{ \text{either } () \text{ or } (v = v_0, f_1, v_1, f_2, v_2, \dots, f_n, u = v_n) : \\ v_i \in X_v, f_i, f \in X_e, s(f_i) = v_{i-1} \cap t(f_i) = v_i \} \quad (1)$$

In words, we take all possible finite paths from v_0 to u so we don't miss any possible compositions. The finitude could maybe be weakened, but I am afraid of what infinite composition might mean. Can there be an infinite path from A to B in our category? I'll just take motivation from group theory and say only finite paths; I understand finite morphism composition. Infinity is a bit too big.

We then define morphism composition as list concatenation. Our lists are finite, and so there are no issues there. We get the bonus, with this notion of composition, to say that the empty list is the identity morphism (trivially). Hence PX is a category.

Now, we need to know what P does on morphisms: Given a **DGraph** morphism $f = (f_E, f_V) : X \rightarrow Y$, $Pf = F$ is a pair of functions (which we will later show is a functor) $F_o : \text{ob}(PX) \rightarrow \text{ob}(PY)$ and $F_m : PX(a, b) \rightarrow PY(F_o(a), F_o(b))$. We can say immediately that $F_o = f_V$. More interestingly, a morphism on dgraphs preserves source and target composition. For any given path, $(a = v_0, f_1, \dots, f_n, b = v_n)$, F_m maps it to $(f_V(a), f_E(f_1), \dots, f_E(f_n), f_V(b))$. We also take the empty list to the empty list. This is sensible, as we know $s_Y \circ f_E = f_V \circ s_X$, and similarly for targets, and so our condition $s_X(f_i) = v_{i-1}$ gives us that $s_Y(f_E(f_i)) = f_V(s_X(f_i)) = f_V(v_{i-1})$, as desired. Hence, F_m seems to do what we want.

Our next step is to show that F is indeed a functor (a morphism in the category **Cat**). F_m clearly takes the identity (empty list) to itself, and also clearly respects composition (concatenation). Hence, F is a functor.

Lastly, we want to show that P is a functor between **DGraph** \rightarrow **Cat**. $P(1_X)$ has components $F_o = f_V$ the identity and F_m the identity as well, just by observing the definition (we know f_E is the identity), and hence $P(1_X) = 1_{PX}$.

This gets a bit weird now, as we need to show that P respects morphism composition from **DGraph** to **Cat**— that it turns dgraph morphisms into functors. Hence, we need to verify what it does on the vertex and edge components OF A DGRAPH MORPHISM. $P(f \circ g)$ has vertex (and hence object) component $(f \circ g)_V = f_V \circ g_V = P(f) \circ P(g)$ by the argument in part 1.

Now, suppose we have $X \xrightarrow{g} Y \xrightarrow{f} Z$ in **DGraph**. Our composition observations from part 1 tells us that we get a function $f \circ g$ with $s_Z \circ (f \circ g)_E = (f \circ g)_V \circ s_X$. This lets us map a path $(x_0, e_1, x_1, \dots, e_n, x_n)$ under P to $(fg_V x_0, fg_E e_1, fg_V x_1, \dots, fg_E e_n, fg_V x_n)$ with confidence that the new path has all the proper criteria to be a morphism in PZ by the argument a few paragraphs up from here. We conclude that the morphism component of $P(f \circ g)$ also satisfies $P(f \circ g) = P(f) \circ P(g)$.

Thus, P respects composition, and is a functor. □
